

## Property Binding.

### HTML:

```
<h1>{{ title }}</h1> <p>{{ message }}</p>
```

### TYPESCRIPT:

```
import { Component } from '@angular/core'; @Component({ selector: 'my-component',  
templateUrl: './my-component.html', }) export class MyComponent { title = 'My Title'; message =  
'My Message'; }
```

This component defines the title and message properties. The templateUrl property specifies the path to the HTML template that will be used to render the component. The templateUrl property points to the my-component.html file, which contains the property binding code. When the component is rendered, the title and message properties will be bound to the {{ title }} and {{ message }} expressions in the HTML template. The result of the expressions will be used to set the values of the title and message properties.
